

Standard Test Method for Tensile-Tear Strength of Bituminous Roofing Membranes¹

This standard is issued under the fixed designation D 4073; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

^{ε1} NOTE—Editorially switched from English dominant to SI dominant.

1. Scope

1.1 This test method covers the determination of the tensile-tear strength of bituminous roofing membranes.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

D 95 Test Method for Water in Petroleum Products and Bituminous Materials by Distillation²

D 2829 Practice for Sampling and Analysis of Built-Up Roofs³

D 3617 Practice for Sampling and Analysis of New Built-Up Roof Membranes³

3. Summary of Test Method

3.1 The tensile-tear strength of a membrane in both longitudinal and transverse directions is determined by measuring the maximum load when notched specimens of specific dimensions are tested to failure at an arbitrary, fixed, tensile strain rate.

4. Significance and Use

4.1 Determining the tensile-tear strength of laboratory and field samples of roofing membranes should be useful in developing performance criteria, and as one basis for comparison of different materials and systems. The effects of temperature, moisture, and aging may be evaluated by appropriate selection of field samples or conditioning of laboratory samples, and tests may be conducted in an environmental chamber.

5. Apparatus

5.1 *Testing Machine*—Universal or standard testing machine with automatic load and strain recording equipment, capable of cross-head movement at a constant rate of 2.54 mm/min (0.100 in./min).

5.2 *Grips*—Self-aligning grips or clamps for holding the test specimen between the stationary member and the movable member or cross-head of the testing machine. Jaw faces of the grips shall be 75 mm (3.0 in.) wide by 50 mm (2.0 in.) deep, shall provide uniform clamping pressure, and shall prevent slippage of the specimen during test.

5.3 *Environmental Chamber*—An insulated chamber with heating and cooling capabilities, designed to enclose the test specimen and clamps so that the temperature may be controlled during a test.

6. Sampling

6.1 *Field Samples*—Field samples shall be taken in accordance with Practice D 2829 or D 3617 but of a size suitable to provide sufficient material for testing in both the machine and cross-machine directions. In cases where field applied aggregate is in place, it shall be removed with a hot scraper such as a putty knife without damaging the top felt. In cases where the insulation facer is a part of the membrane system it should be included and so reported.

6.2 Laboratory Samples:

6.2.1 Condition all components at $23 \pm 2^\circ\text{C}$ ($74 \pm 4^\circ\text{F}$) and $50 \pm 5\%$ relative humidity for a minimum of 72 h prior to constructing the membrane sample.

6.2.2 Prepare sample membranes approximately 300 by 500 mm (12 by 20 in.) as required by the roof specifications being tested, exclusive of aggregate.

6.2.3 The quantity of bitumen in any layer shall be within 10 % of the quantity specified and the entire sample shall be within 5 %. (These requirements apply to laboratory prepared samples only.)

7. Test Specimen

7.1 Cut at least three test specimens, in each orientation to be tested, of the laboratory prepared or field sampled membrane with a die or a sharp razor-knife using a metal template to produce the shape shown in Fig. 1.

7.2 Specimens shall contain in the notch area (see Fig. 1) the

¹ This test method is under the jurisdiction of ASTM Committee D-8 on Roofing, Waterproofing, and Bituminous Materials and is the direct responsibility of Subcommittee D08.20 on Nonstructural Roof Systems.

FIG. 1 Tensile Tear Specimen

9. Procedure

9.1 Establish the desired conditions in the environmental chamber, if used, and set the jaws of the self-aligning grips 100 mm (4 in.) apart. Clamp the test specimen in the jaws so that the jaw faces cover a 75 mm (3 in.) wide by 50 mm (2 in.) deep area of the specimen at each end.

9.2 Start the testing machine and break the specimen in tension with a constant rate of cross-head movement of 2.54 mm/min (0.100 in./min). Record the maximum load in pounds-force (newtons) as the tensile-tear strength of the specimen.

9.3 Determine the moisture content of specimens in accordance with Test Method D 95 immediately after breaking. Any moisture condensed on the surface of the specimen should be removed prior to testing moisture content.

9.4 Unless another temperature is specified, test specimens at $23 \pm 2^\circ\text{C}$ ($74 \pm 4^\circ\text{F}$).

10. Report

10.1 The report shall include the following:

10.1.1 Complete description of the membrane tested, including identification of all components if possible.

10.1.2 Source and location from which field samples were obtained, the date obtained, and the date constructed; for laboratory samples, the date constructed.

10.1.3 Conditioning and testing procedure followed, including temperature and humidity, and the date of test.

10.1.4 Tensile-tear strength of each specimen, and the average values in each direction for not less than three specimens.

10.1.5 Moisture content of specimens.

11. Precision

11.1 *Precision*—Because of the variations in felts and fabrics, repeatability and reproducibility may vary depending upon the type of felt or fabric and the number of plies in the membrane. Reproducibility may be expected to vary approximately 7 % about the mean for similar samples.

11.2 *Bias*—Since there is no accepted reference material suitable for determining the bias for this test method, bias has not been determined.

12. Keywords

12.1 bituminous roofing membranes; field and laboratory samples; tensile-tear strength

minimum number of plies specified for the membrane.

8. Conditioning

8.1 Maintain specimens cut from field samples “as received,” or condition them for 72 h at any desired temperature and humidity prior to testing under those conditions.

8.2 Condition specimens cut from laboratory prepared samples for a minimum of 72 h at $23 \pm 2^\circ\text{C}$ ($74 \pm 4^\circ\text{F}$) and $50 \pm 5\%$ relative humidity, or any desired temperature and humidity prior to testing under those conditions.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 100 Barr Harbor Drive, West Conshohocken, PA 19428.
